Abstract

Background

Cellular functions are regulated by complex webs of interactions that might be schematically represented as networks. Two major examples are transcriptional regulatory networks, describing the interactions among transcription factors and their targets, and protein-protein interaction networks. Some patterns, dubbed motifs, have been found to be statistically over-represented when biological networks are compared to randomized versions thereof.

Their function *in vitro* has been analyzed both experimentally and theoretically, but their functional role *in vivo*, that is, within the full network, and the resulting evolutionary pressures remain largely to be examined.

Biological Network are Complex

They have a **non-random topology**.

They are resistant to **random damages**.

They are resistant to **noise**.

They are ... **huge**.

How to deal with them?

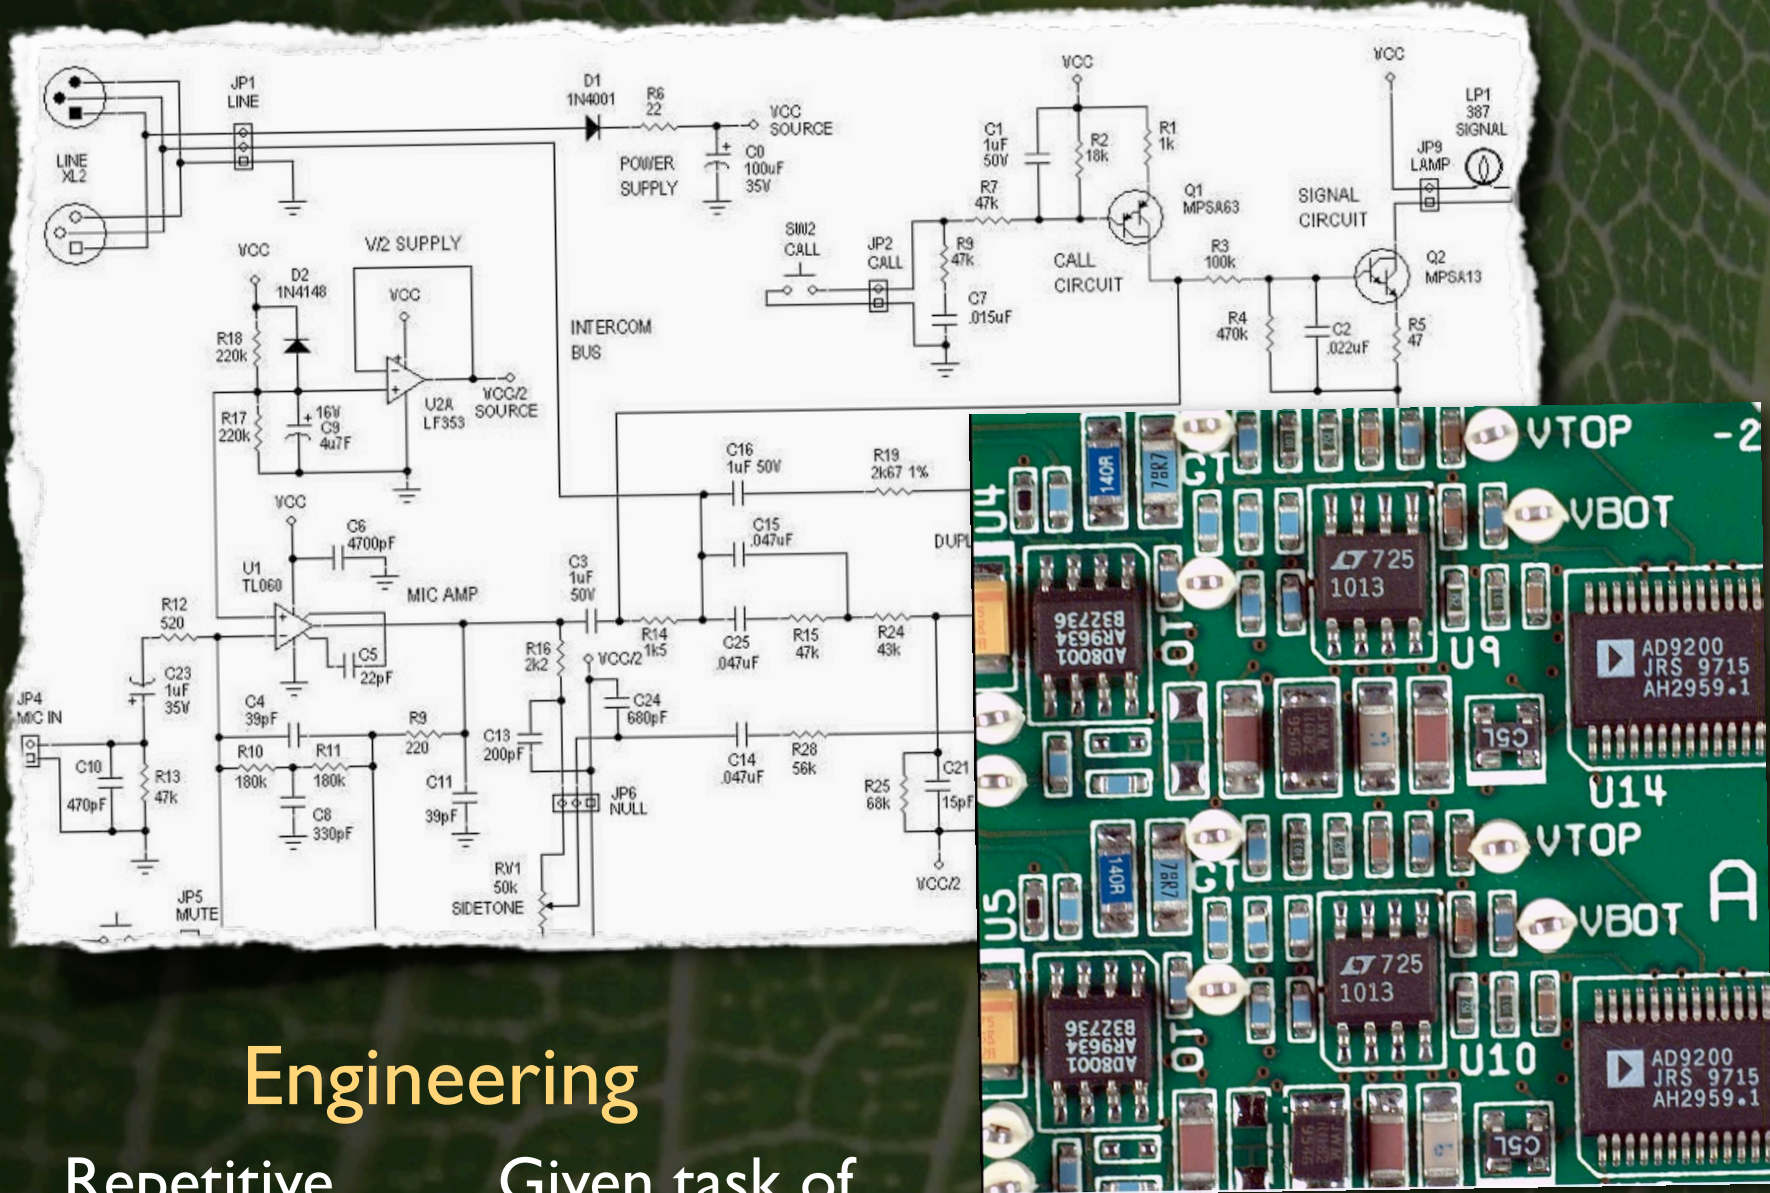

Reductionist approach: let's decompose them into tractable **smaller elements**.

Two approaches: **motifs** and **modules**.

Network **Motifs**

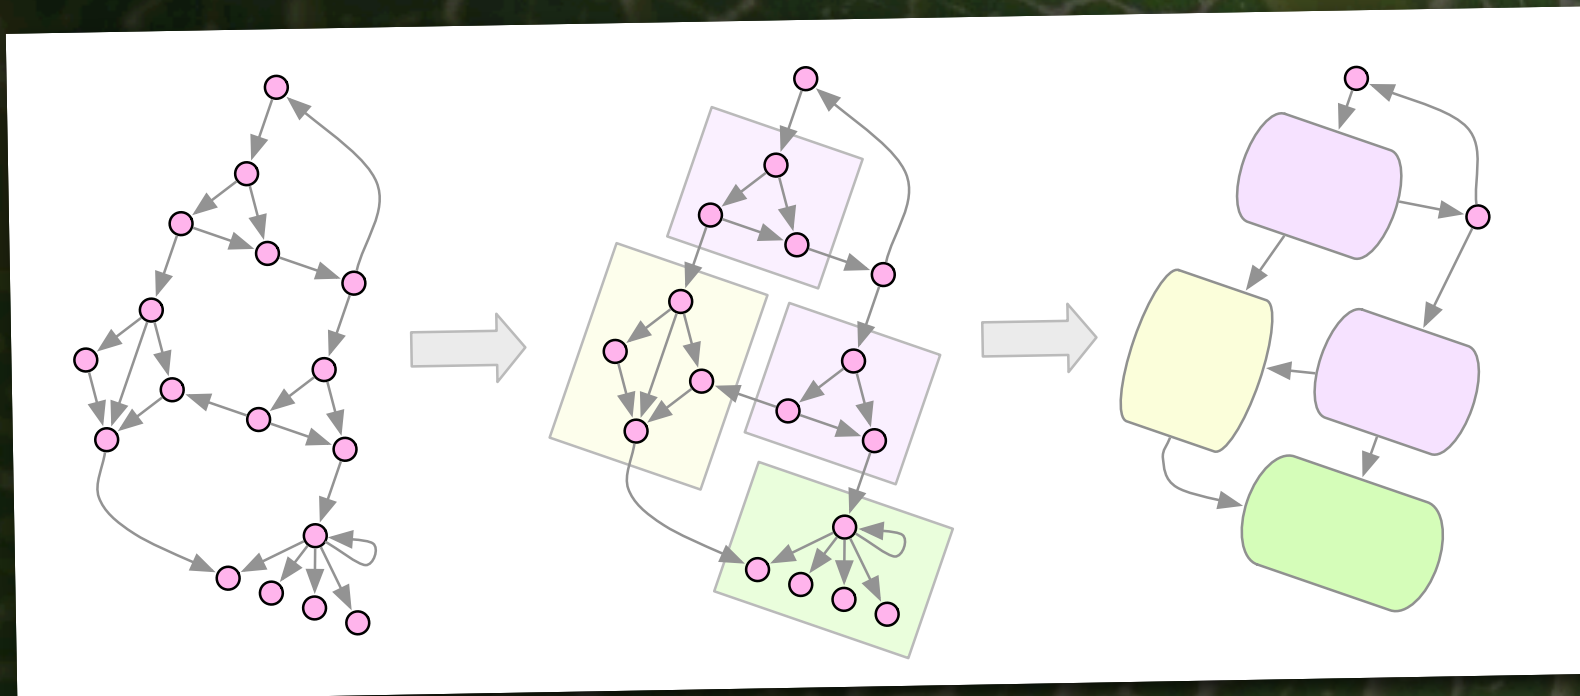

Engineering

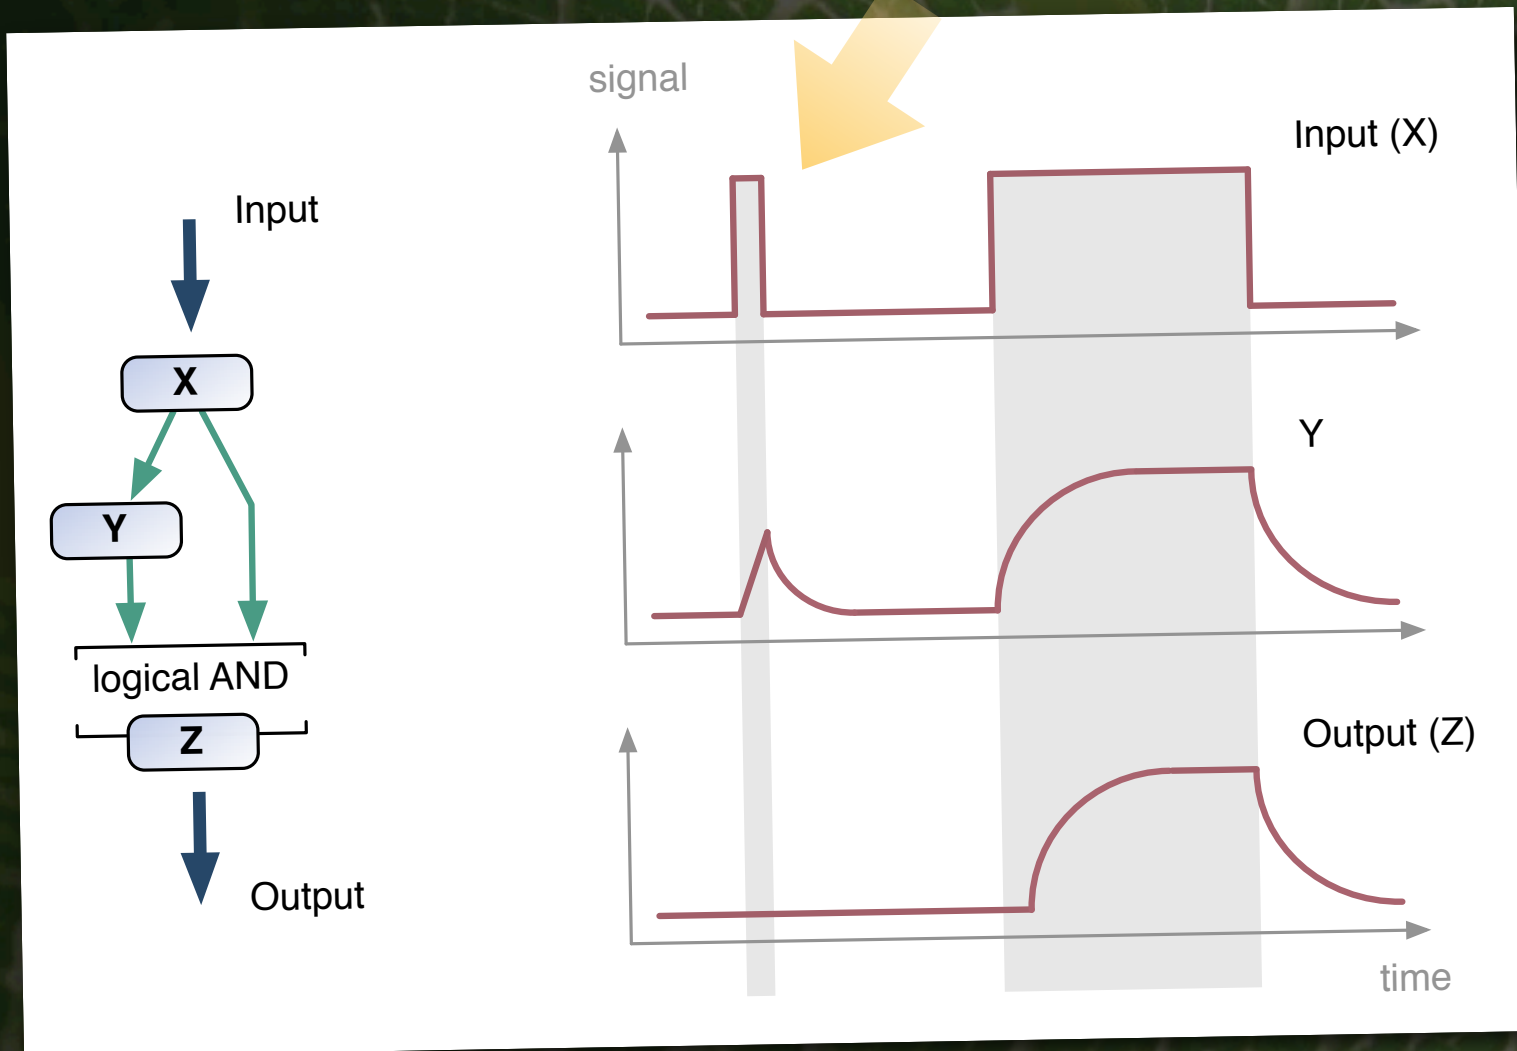

Repetitive structure = Given task of signal processing

What about biological networks?

- ‘Signal’ could be **gene activity level**
- ‘Circuits’ could be **gene regulatory networks**

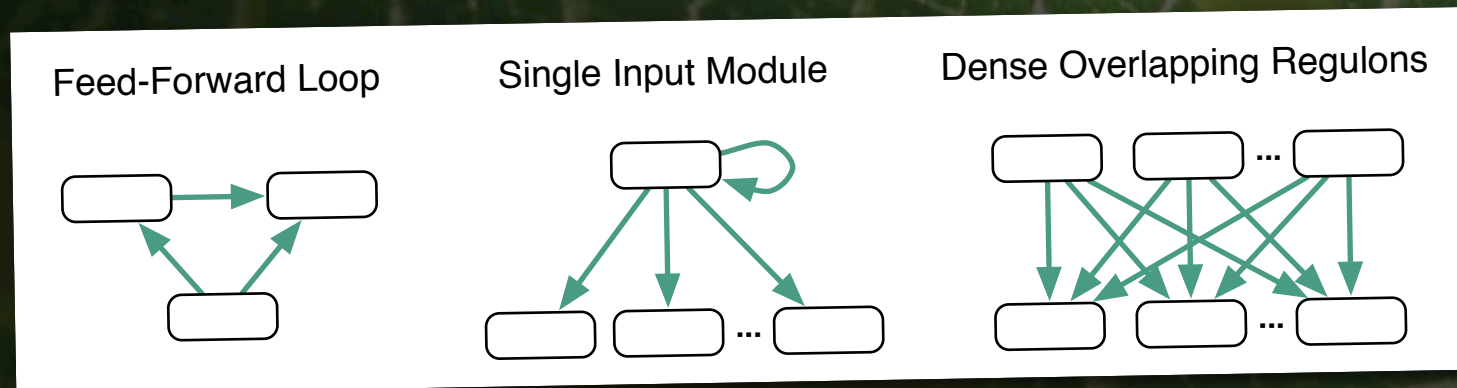

Candidate: the feed-forward loop

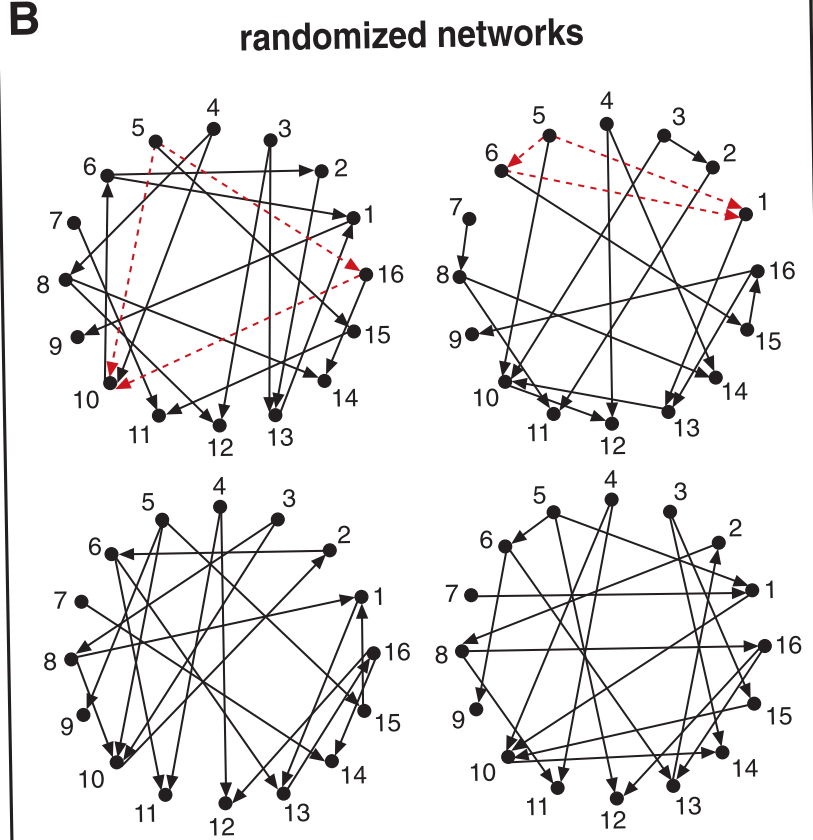

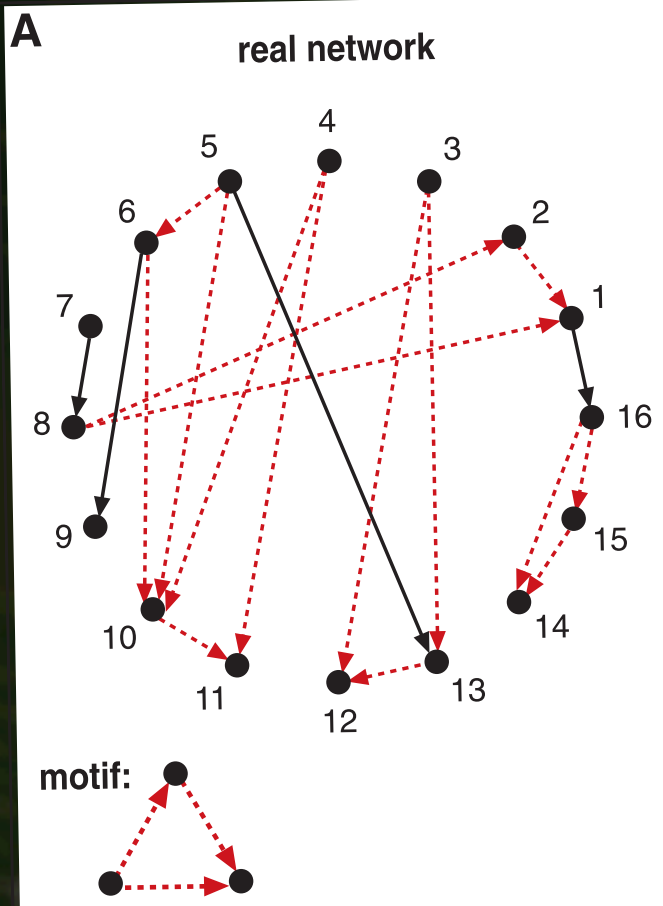

Repeated subgraphs have been found

- In **gene regulatory networks**
- In **protein interaction networks**

They are **over-represented** when compared to **randomized networks**.

Simple and **intuitive** hypothesis of how biological networks are structured to **process information**.

Detailed dynamic models of motifs have been proposed *in silico* (mainly FFLs).

Numerous algorithms have been proposed to **efficiently search for motifs** in any network.

But ...

Are they real **building blocks** of biological systems? Are motifs **biologically relevant**?

Step I: Identification of 'rich' network motifs

II.1

II.2

II.3

II.4

III.1

III.2

III.3

III.4

III.5

III.6

III.7

III.8

Step 2. Phylogenetic study

Biologist's claim:

Functional interactions between genes should correspond to a **selective pressure** that **preserves** this interaction.

Evaluation in five yeast species.

co-evolution score

	1	2	3	4	5
random triples	1888	1884	3280	2428	521
linked genes triples	1337	1229	2212	1513	3669
motifs	78	59	106	77	160

Step 3. Functional study

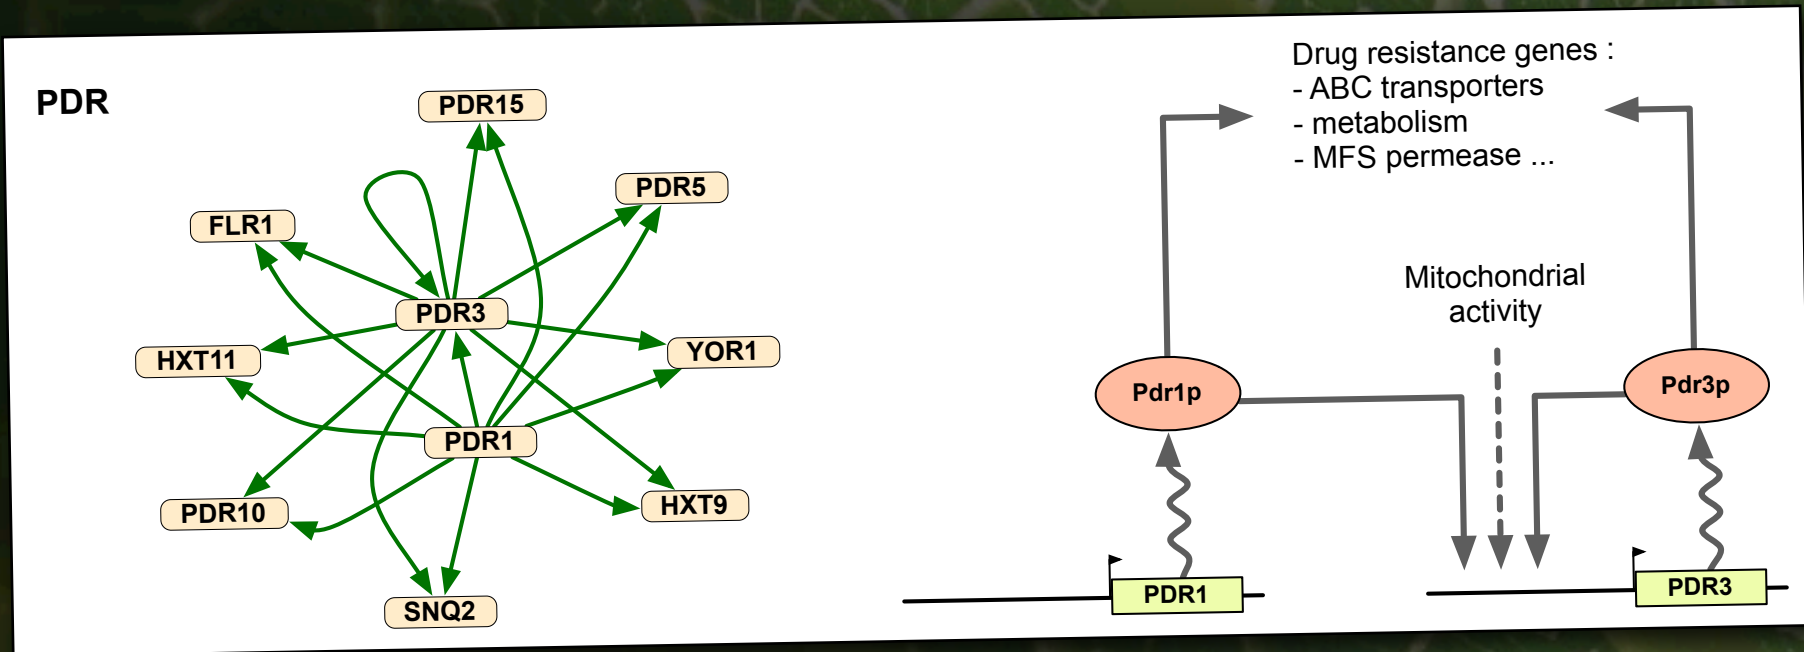

Biologist's claim:

Identified **motifs instances** must play a **key role** in the **regulation** of biological processes.

Evaluation in five well known systems.

Pleiotropic drug resistance system

- Pdr1 and Pdr3 respond to **different signals**
 - They're never active at the same time
 - **No evidence of cooperativity** on the targets
- > These motifs do not exist in practice.

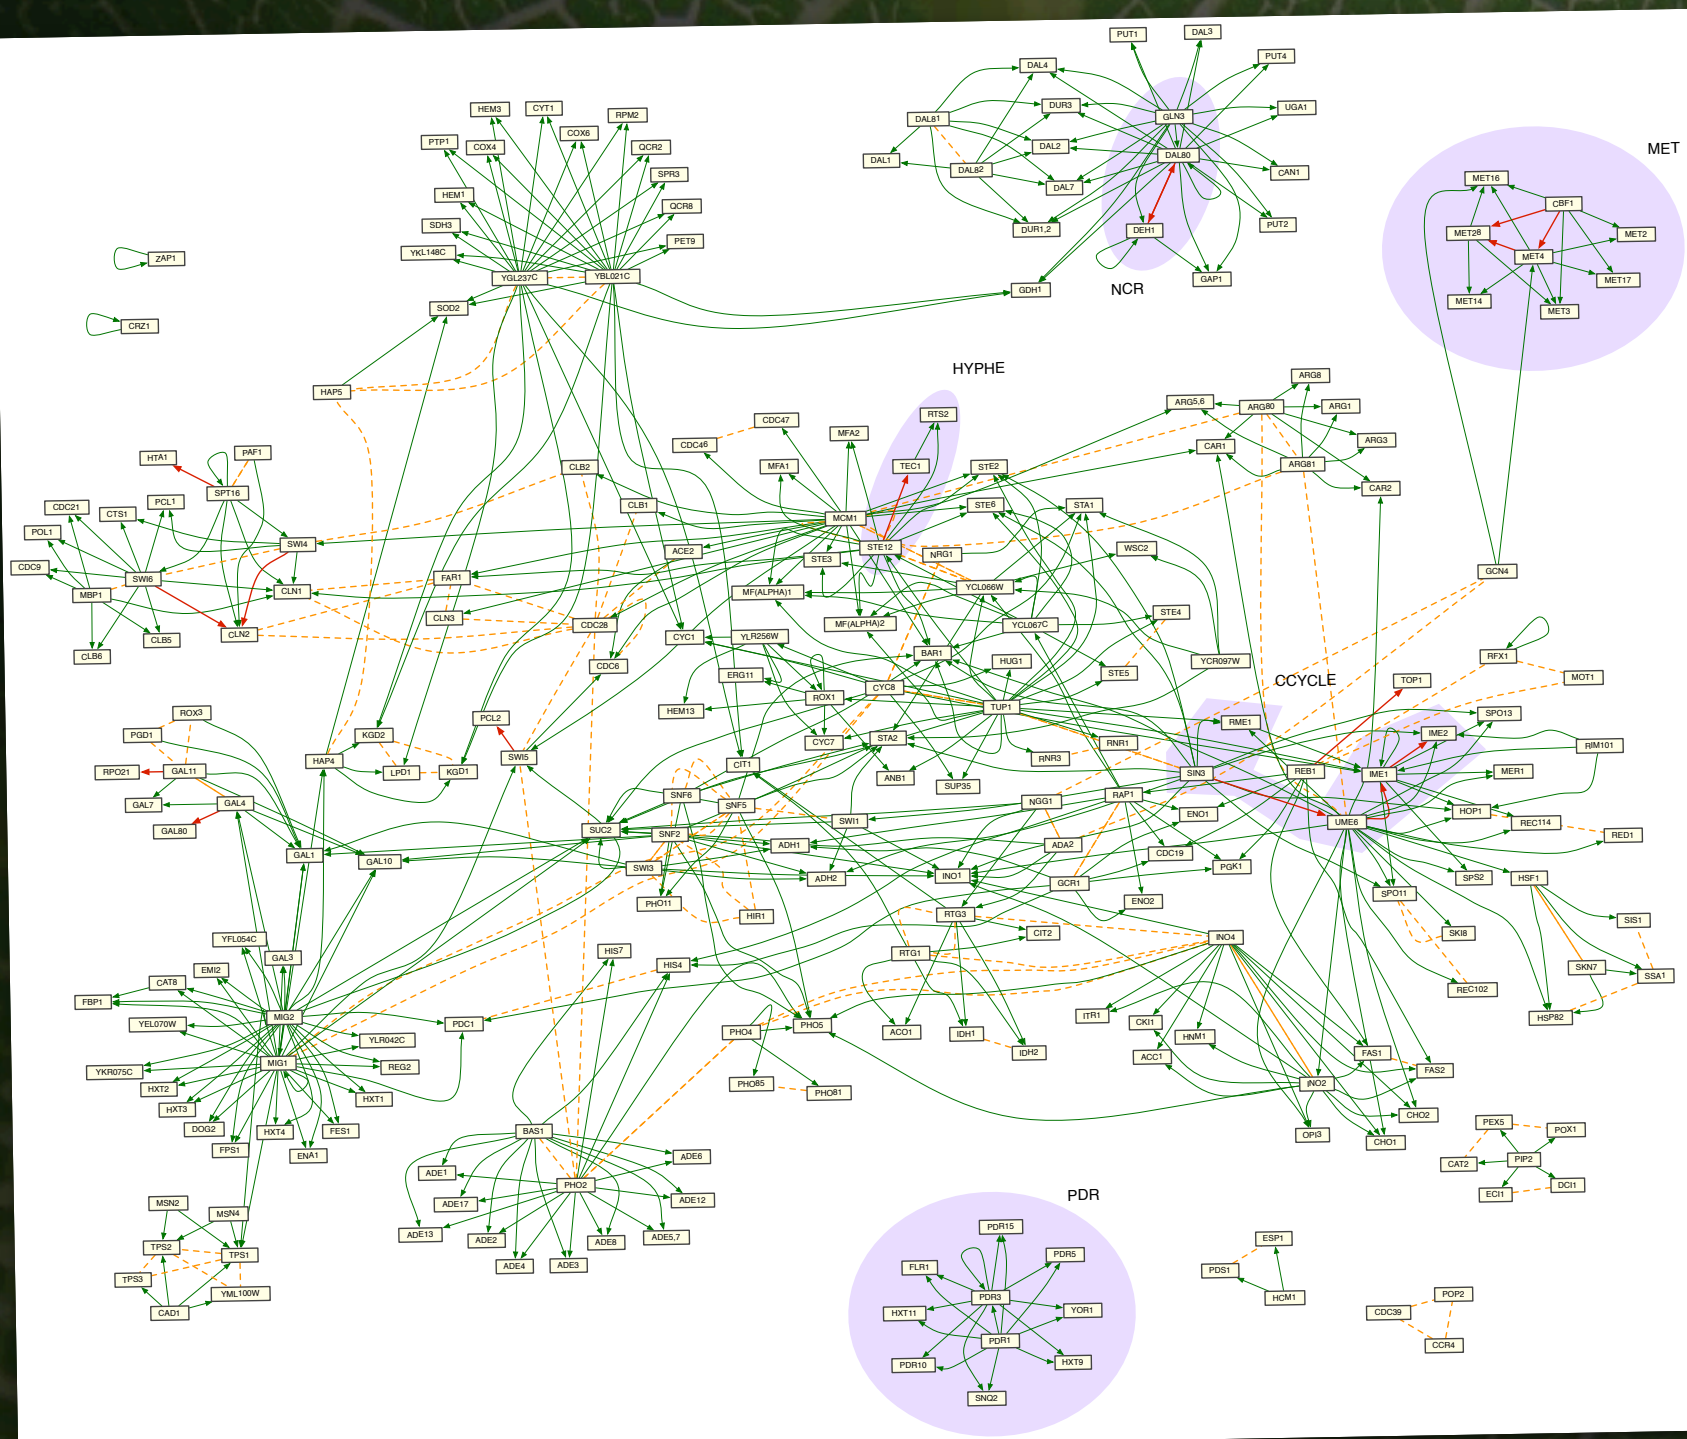

Biases 1 & 2

Most network representations don't distinguish **linear** from **non-linear** interactions

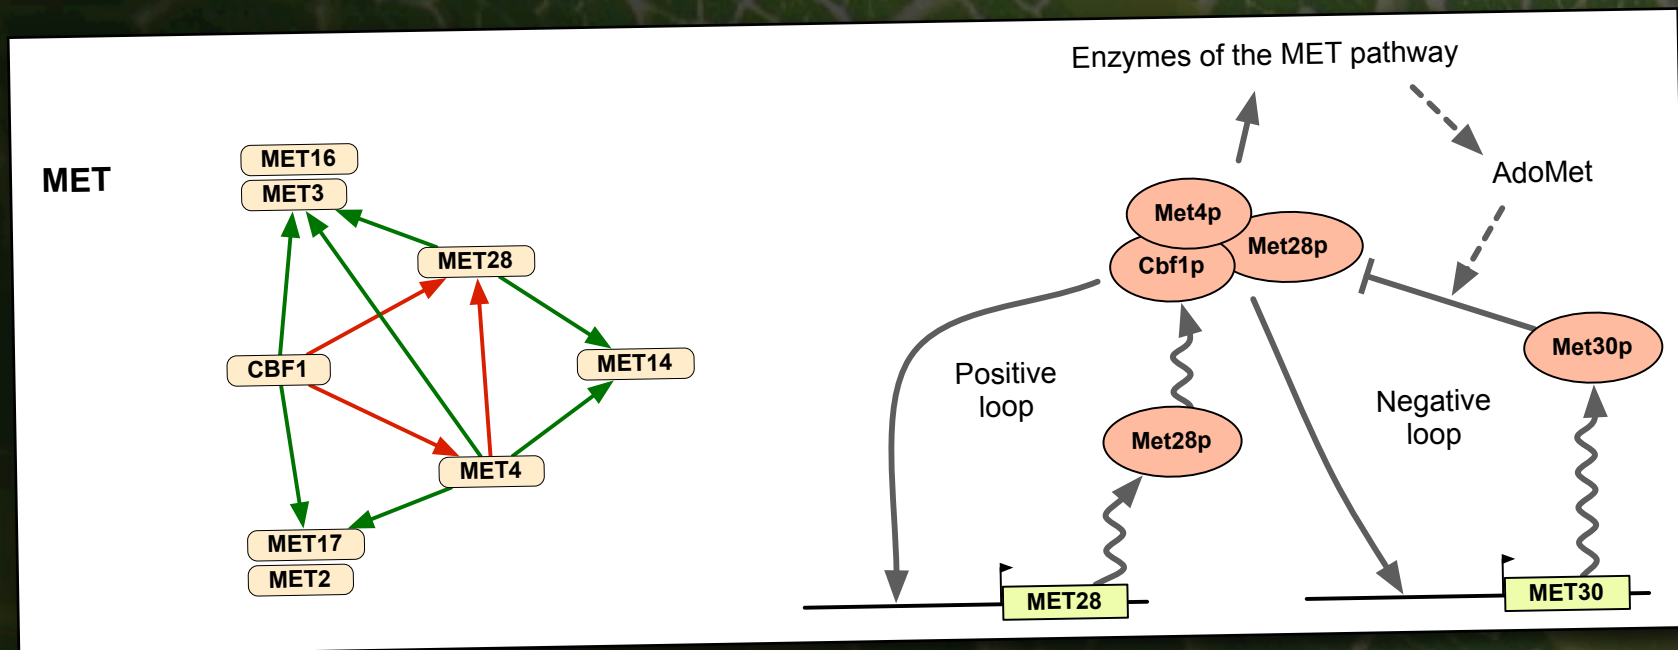

- *pdr1* and *pdr3* don't cooperate on their targets

Network motifs do not exist in **isolation**

- *pdr3* have its own regulation schedule, which destroy any property these FFL could have

The methionine pathway

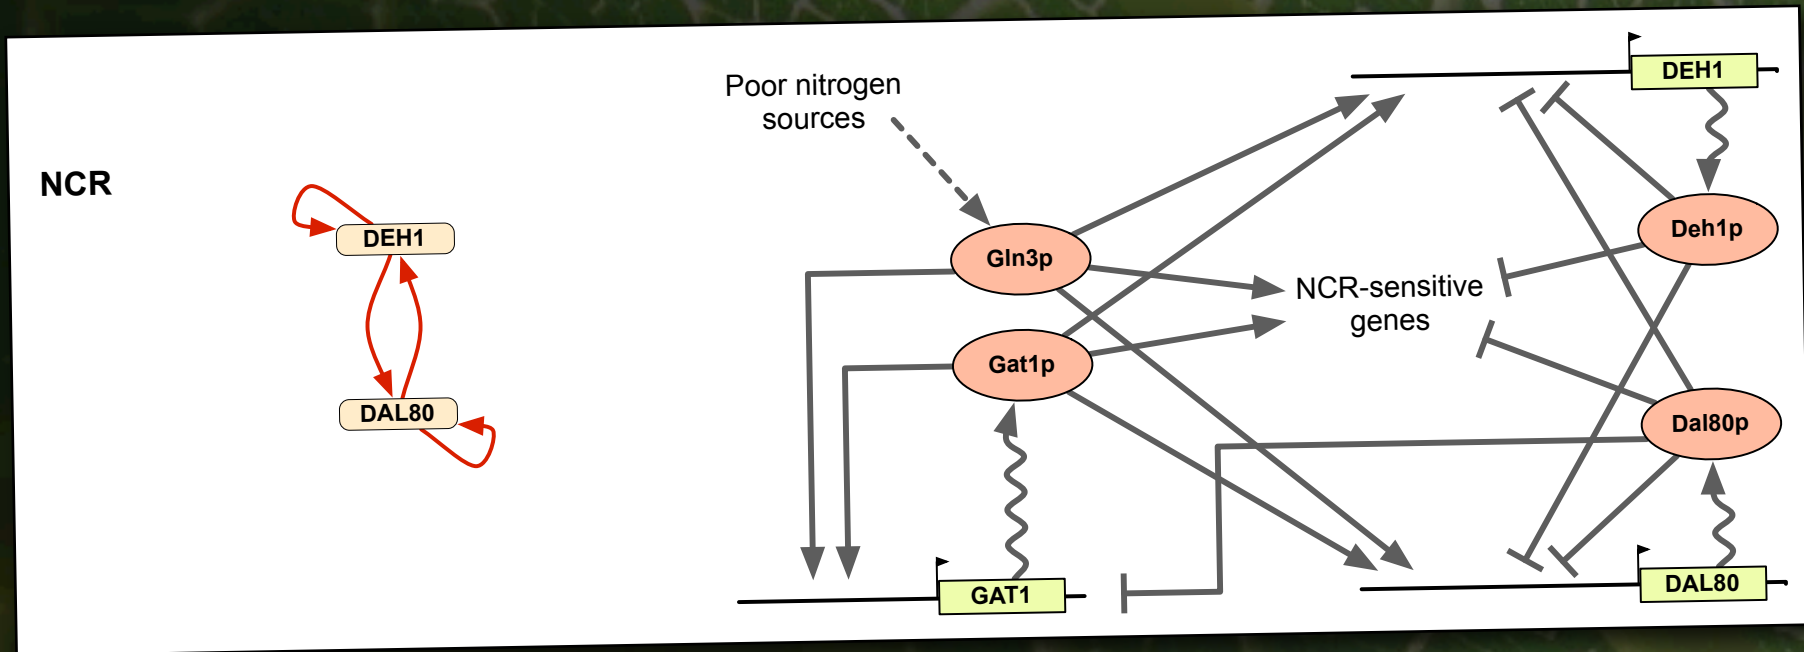

- Cbf1 and Met28 have **no regulatory activity**
 - The key regulatory mechanisms (loops) are **not captured** by the motifs found
- > These motifs do not exist in practice.

Bias 3

Most network representations don't deal with **transient objects**, like **protein complexes**.

- *cbf1, met4 and met28, while in complex, spuriously **inherited** the regulatory activity of met4, artificially **creating motifs***

The nitrogen catabolite repression system

- The key regulatory mechanisms (oscillation between Gln3p/Gat1p and Deh1p/Dal80p) are **not captured** by the motifs found
- > This motif exists but have no role in practice.

Bias 4

Not all over-represented motifs are significant.

- *deh1p* and *dal80p* are **paralogs** of an ancestor protein with homo-dimerization capability
- The duplication is **too recent** for the function of these two proteins to have **diverged**

Conclusion

Motifs do not seem to be biologically relevant.
They either **do not exist** or have **no role**.

But motifs **are** statistically significant ... aren't they?

Counter argument

The existence of over-represented subgraphs is a **consequence of the network growth**, without need of any hypothesis of selection along evolution.

- Artzy-Randrup Y, Fleishman SJ, Ben-Tal N, Stone L
Comment on "Network motifs: simple building blocks of complex networks" and "Superfamilies of evolved and designed networks" Science 2004, 305:1107
- Banzhaf W and Kuo P D, *Network motifs in natural and artificial transcriptional regulatory networks* Journal of Biological Physics and Chemistry, 4 (2004) pp. 85 - 92

Take-home messages

Beware of artifacts from network representation!

- Networks are **static**, i.e. they superpose **all existing** (and not necessarily **co-occurring**) interactions
- Networks are not rich enough to represent **non-linearities** and **transient objects**. Examples of gene regulation logic and protein complexes

Don't rely too much on the **topology** of networks.

Beware of statistical significance!

- Biological systems **are not designed**, they're the result of trial-and-errors over billions of years. They contains **lot of structures**, that are not necessarily (or no more) of use.

Don't rely too much on the **abundance** of an object to judge of its relevance. Ask the question of the **biological** relevance.

Alternative to motifs?

The idea of small structures performing signal-processing tasks is actually **good**.

We biologists **expect** such tasks to be performed: signal conversion, memorization, amplification, extinction, discretization, integration, etc.

Idea

To make a clear separation between structure and function: distinguish **tasks** from **implementations**.

Implementations: the particular **molecular mechanisms** used to perform these tasks.

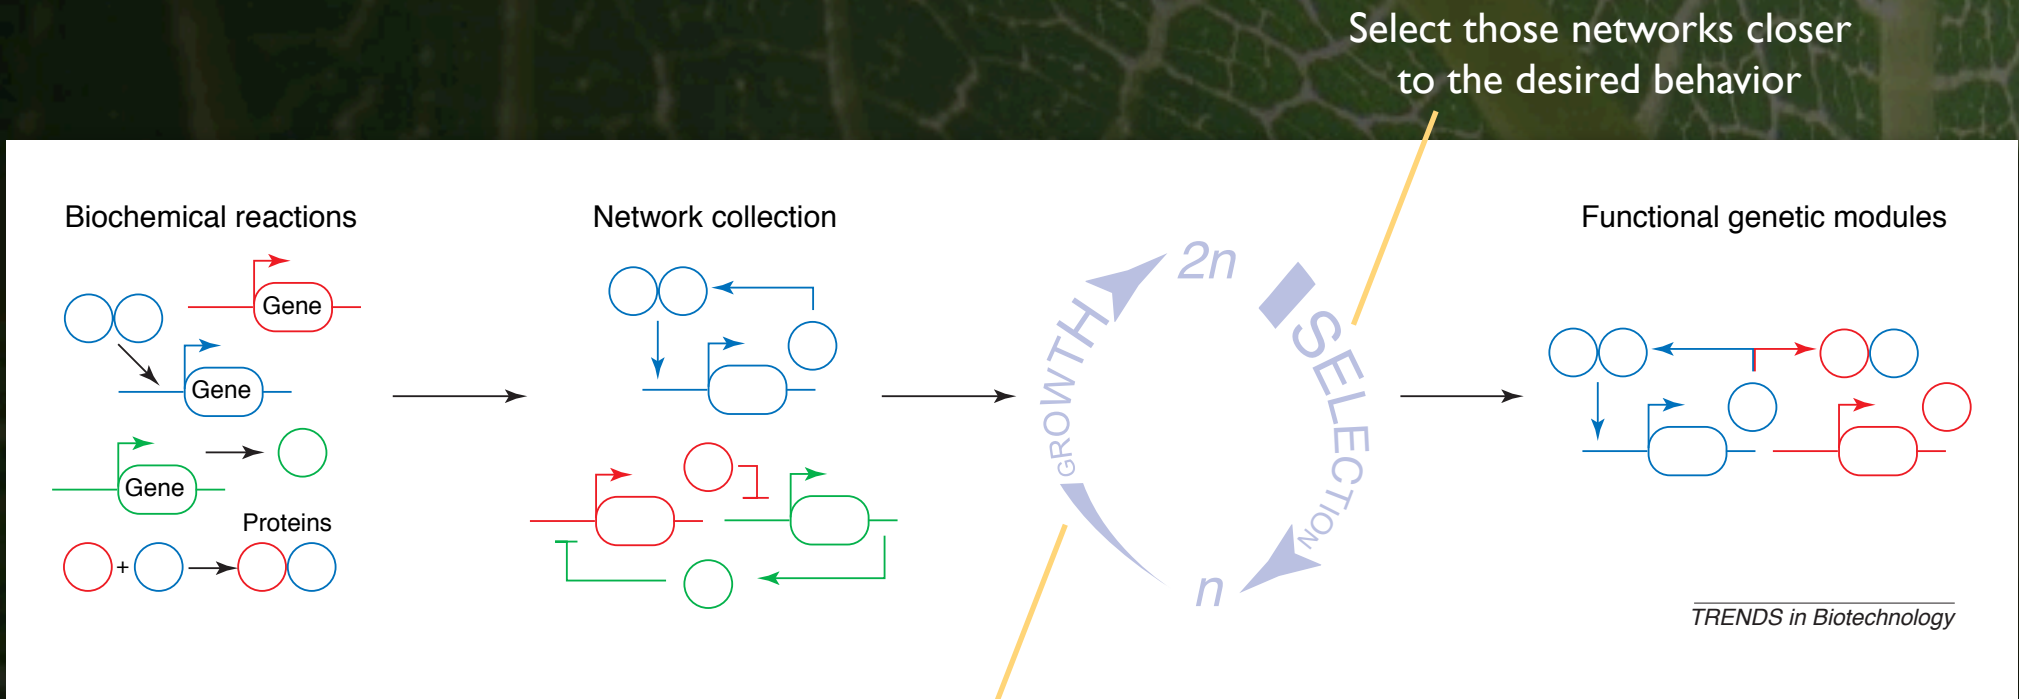

New approach

We must look for tasks, not implementations.

Rationale

It have been shown that a single task can be implemented with **many different mechanisms** with **distinct topologies**.

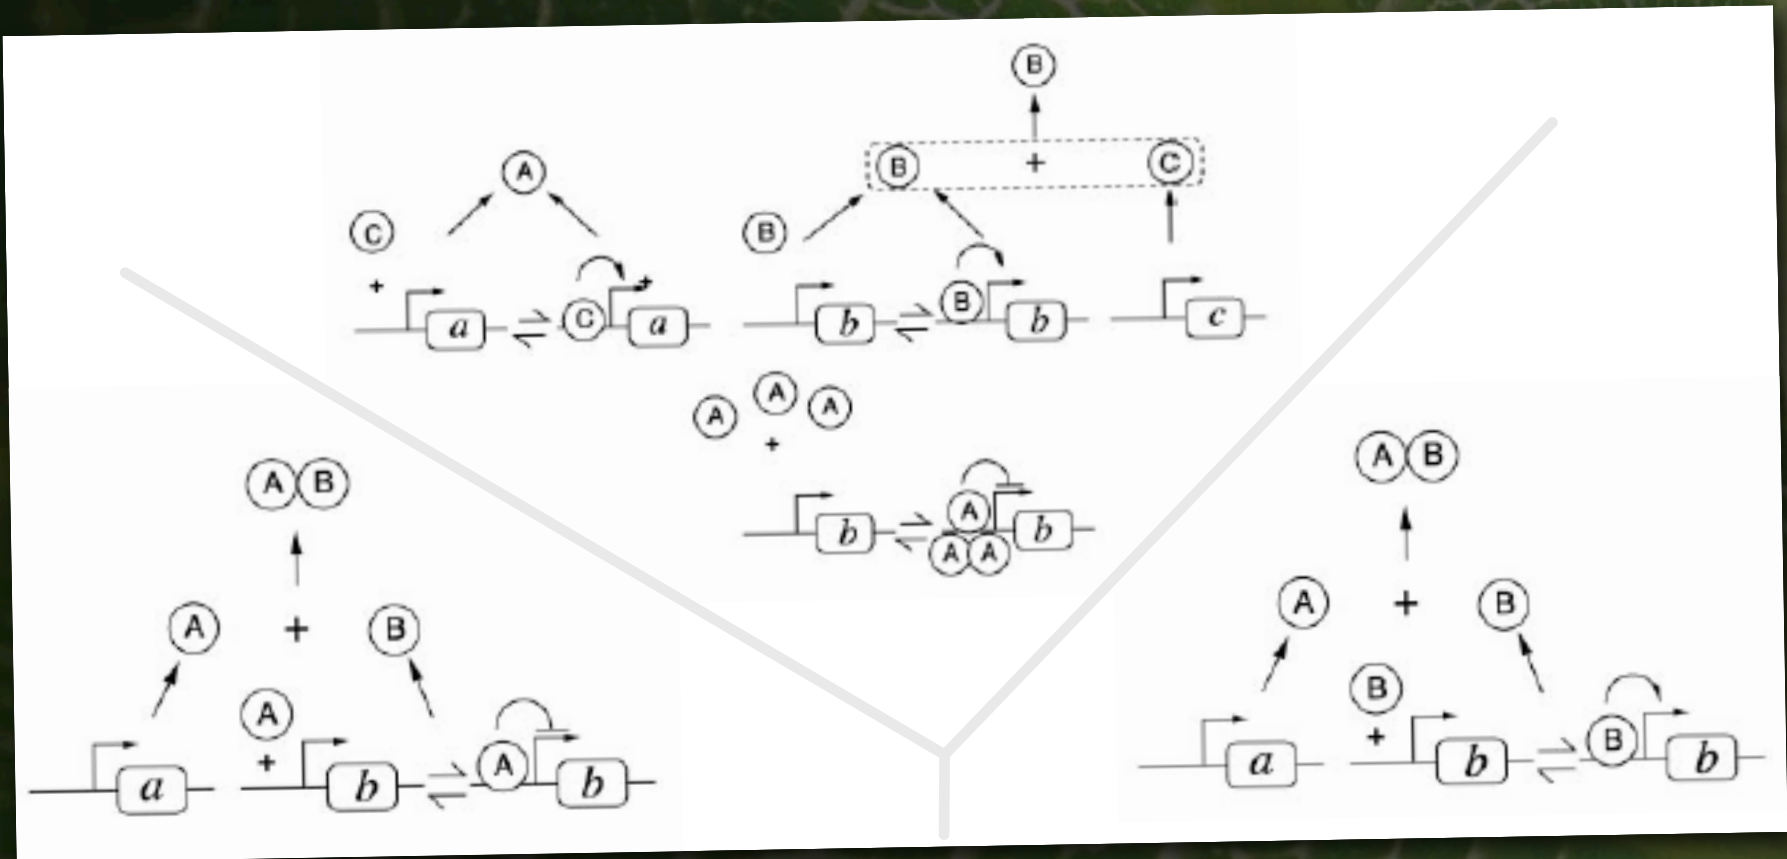

François P, Hakim V *Design of genetic networks with specified functions by evolution in silico* PNAS 2004 vol. 101, 580–585

Randomly evolve network structure and kinetic constants

Select those networks closer to the desired behavior

Implementation of a **toggle switch**
